Reliability based design procedures for design of transmission line structures to resist wind load require statistical information on several quantities related to wind and wind-structure interactions. These quantities include wind climate, height and terrain effects on wind speed, gust and turbulence effects on the structure, force coefficients, load combinations of wind and ice, and structural response of the transmission line to load.

System Reliability Analysis with Reliability Block Diagrams (RBDs) can be used in lieu of testing an entire system by relying on the information and probabilistic models developed on the component or subsystem level to model the overall reliability of the system. It can also be used to identify weak areas of the system, find optimum reliability allocation schemes, compare different designs and to perform auxiliary analysis such as availability analysis (by combining maintainability and ...

Optimizing reliability of a design. Reliability-based Design Optimization (RBDO) uses the mean values of the random system parameters as design variables, and optimizes the objective function subject to predefined probabilistic constraints (such as failure probability or reliability index). As a result, an RBDO solution not only provides an improved design, but also a higher degree of confidence in the design.
